

CHECKLIST

Build bulletproof *offline sync*

A complete architectural checklist to keep your mobile application reliable when the internet drops.

01

Choose local storage wisely

Use lightweight databases like SQLite, Realm, or WatermelonDB instead of storing massive JSON strings in basic key-value storage.

02

Implement UUID generation

Generate unique IDs on the client device. This prevents primary key conflicts when multiple offline devices sync with your database simultaneously.

03

Use queue-based operations

Track mutations in an offline queue. Replay those exact actions in order when connection is restored instead of just sending the final state.

04

Design clear conflict rules

Determine who wins ahead of time. Use last-write-wins or build custom server-side merge strategies to handle overlapping user updates.

Ready to *build*?

Comment BUILD or DM us your idea. The OpenXcode team will reply with a rough approach and timeline.

Comment *BUILD* to start.
